Abstract

Objective: In this study, we evaluated subcutaneous (sc) morphine in combination with multimodal analgesia for postoperative pain control after radical nephrectomy and pyeloplasty with flank incision.

Methods: Forty-nine patients under The American Society of Anesthesiologists Physical Status classification (ASA) I-III aged 18-85 years undergoing radical nephrectomy and pyeloplasty with flank incision were included in this prospective, randomised study. The patients were divided into two groups (Group O [n=25] and Group M [n=24]) and received standard general anaesthesia. Tramadol (100 mg) and paracetamol (100 mg) were given intravenously before fascia closure and 20 mL of 0.25% levobupivacaine was injected locally at surgical incisions in all patients. Patients in Group M also received 0.1 mg kg⁻¹ morphine subcutaneously. Patient-controlled analgesia (PCA) with tramadol was used for postoperative pain control in both groups. Postoperative pain scores (VAS), vital parameters, side effects, the need for rescue analgesia during 24 hours postoperatively, and patient satisfaction were recorded.

Results: Groups were comparable with respect to demographic data, ASA status, and duration of surgery. There were no significant differences between the groups in postoperative PCA tramadol consumption, rescue analgesia, side effects, or vital parameters. Postoperative pain scores (VAS) in Group M were significantly lower at 30, 45, 60, and 120 minutes compared to Group O (p<0.05).

Conclusion: In patients undergoing radical nephrectomy and pyeloplasty with flank incision, subcutaneous morphine in combination with multimodal analgesia decreases early postoperative pain scores compared to multimodal analgesia alone.

Key Words: Subcutaneous, morphine, postoperative pain, flank incision
Anesthesia induction in the patients that did not undergo premedication was performed with intravenous (iv) 0.5 mg atropine, iv 2 mg kg⁻¹ propofol, iv 1 µg kg⁻¹ remifentanil for 30-60 seconds (sec) and iv 0.6 mg kg⁻¹ rocuronium, and maintenance was provided by O₂, air, and sevoflurane and iv infusion of 0.25 µg kg⁻¹ min⁻¹ remifentanil. Before the closure of fascia after the procedure, sc 0.1 mg kg⁻¹ morphine was administered through the deltoid muscle in the patients in Group M. No additional procedure was performed in the patients in Group O. Then, during the closure of the fascia at the end of surgery, 100 mg tramadol and 1 g/100 mL paracetamol was administered in all patients by slow infusion (not shorter than 20 min.). During skin closure, incision line was infiltrated by 20 mL of 0.25% levobupivacaine. Decurarization was provided by iv 0.5 mg atropine and iv 1.0 mg neostigmine. Postoperative pain was controlled in all patients by patient-controlled analgesia (PCA) (tramadol PCA; 4 amp tramadol 100 mg/100 mL in 0.9% NaCl, bolus 20 mg, lock time 15 min., 4-hour limit: 200 mg). In the postoperative period, iv 1 g/100 mL paracetamol was administered by slow infusion (not shorter than 20 min) within the first 24 hours repeating at 6-hour intervals. Scores of visual analogue scale (VAS; 0=no pain and 10=maximum pain), vital signs, and side events (nausea, vomiting) were recorded for the postoperative 24 hours at minutes 0, 15, 30 and 60 and at hours 2, 4, 6, 12 and 24. At the end of the first 24 hours, use of tramadol for PCA and patient satisfaction (very well, good, moderate and poor) were assessed. For severe pain (VAS >4) in the postoperative period, im diclofenac Na was administered as an additional analgesic. Patients with persistent pain (VAS >4) received iv 50 mg pethidine HCl.

Statistical analysis
For the statistical analysis of data, Chi-Square test was used for gender, ASA, patient satisfaction and adverse events, whereas independent samples test was used to evaluate other variables.

Results
Demographic characteristics, ASA classification, and duration of surgery were similar in all patients (Table 1). No differences were determined between the groups in terms of using postoperative tramadol for PCA and need for additional analgesic (diclofenac Na) (Table 2). Postoperative pain score was significantly lower at minute 30, 45, and 60 and at hour 2 in the group received postoperative sc morphine as compared to the control group (Figure 1). The groups were similar in terms of adverse event (nausea and vomiting) and patient satisfaction. Pruritus was not observed in any of the patients in the morphine group (Table 2). No significant difference was found between the groups in terms of hemodynamic variables.

Discussion
Patients have severe postoperative pain after surgical interventions performed by flank incision due to the incision of many muscles (5). Postoperative pain influences patient comfort and satisfaction and prolongs duration of hospital stay and enhances post-procedure complications (6). Postoperative maximum pain is seen within the first 9-12 hours also following general anaesthesia (7). Thus, effective analgesia in the early postoperative period is of great importance in the patients undergoing surgery by flank incision.

Stronger analgesia and lower adverse event with concurrent use of different classes of analgesics with diverse mechanisms of action is an important part of current pain treatment (5, 6, 8). Thereby, adverse effects of drugs are aimed to minimize by means of using them at appropriate dose due to their contribution of analgesic drugs with different mechanism of action to each other and their synergistic effects (9). Thus, complications are lowered, satisfaction is enhanced, and duration of hospital stay is shortened (10).

Infiltration of wound site with local anaesthetic agents, which is one of the simplest and most effective ways of postoperative pain treatment, may prolong duration of postoperative analgesia (11, 12). Besides, the combination of paracetamol and tramadol has been used in many studies due to high analgesic efficacy with low adverse effect and its efficacy has been proven (13-16). Moreover, although sc and iv administration of morphine have similar clinical effect and efficacy (17, 18), Stuart-Harris et al. (19) reported that morphine-6-glucuronate (M6G) and morphine-3-glucuronate (M3G), which are active metabolites of morphine, occurred in high amounts after iv administration of morphine. Among these active me-

ASA: Physical status scoring by American Society of Anesthesiologists
Morphine at a dose of 0.5 mg kg$^{-1}$ administered via sc route in addition to local anaesthetic infiltration and iv paracetamol and tramadol for postoperative pain control in the patients who underwent nephrectomy and pyeloplasty by flank incision lowered the early postoperative pain scores and it was safe at that dose.

**Ethics Committee Approval:** Ethics committee approval was received for this study from the ethics committee of Ege University School of Medicine (05.01.2010, 09-11.1/32).

**Informed Consent:** Written informed consent was obtained from patients who participated in this study.

**Peer-review:** Externally peer-reviewed.

**Conflict of Interest:** No conflict of interest was declared by the authors.

**Financial Disclosure:** The authors declared that this study has received no financial support.
