

Stellat ganglion blockage in the treatment of chronic refractory angina pectoris

Kronik refrakter angina pektoris tedavisinde stellat ganglion blokajı

● Ferdi GÜLAŞTI,¹ ● Sevil GÜLAŞTI,² ● Sinem SARI,³ ● Osman Nuri AYDIN⁴

Summary

Medical approach to treatment of chronic refractory angina pectoris, laser revascularization, transmyocardial laser revascularization, angiogenesis, growth factor gene therapy, thoracal epidural anaesthesia, and spinal cord simulator are used, but unilateral left stellat ganglion block is recommended as an alternative. In addition to a complete medical history and physical examination, diagnostic procedures for renal cell cancer may include the following: We present the case of a 66-year-old male patient who underwent unilateral left stellate ganglion blockade in the treatment of chronic refractory angina pectoris.

Keywords: Chronic refractory angina pectoris; late heart failure; palliative treatment; unilateral left stellat ganglion blockade.

Özet

Kronik refrakter angina pektoris tedavisine medikal yaklaşım, lazer revaskülarizasyon, transmyokardial lazer revaskülarizasyon, angiogenesis, growth faktör gen terapisi, torakal epidural anestezi ve spinal kord simülatörü kullanılmakla birlikte, unilateral sol stellat ganglion blokajı bir alternatif olarak önerilmektedir. Özellikle yaşam süresi kısa olan hastalarda tercih edilebilecek bir palyatif bir girişim olarak düşünülmelidir. Bizde 66 yaşında erkek hasta son dönem kalp yetersizliği ile takip edilen ve kronik refrakter angina pektorisin tedavisinde unilateral sol stellat ganglion blokajı yapılan olguyu sunduk.

Anahtar sözcükler: Kronik refrakter angina pektoris; son dönem kalp yetmezliği; palyatif tedavi; unilateral sol stellat ganglion blokajı.

Introduction

In recent years, due to the improvements in the treatment of coronary artery disease and other areas of medicine, life expectancy is increasing and the number of patients with cardiac disease is increasing. In addition to medical treatment, unilateral left stellate ganglion blockade can be used to treat angina-related chest pain. Although the use of chronic refractory angina pectoris is not common in patients with no curative cardiac treatment chances, unilateral left stellate ganglion blockade is an attempt to achieve palliative success.

We present a patient with chronic refractory angina pectoris who has recently been diagnosed with

heart failure and who underwent unilateral left stellate ganglion blockade.

Case Report

A 66-year-old male patient admitted to the emergency room with chest pain and shortness of breath. The patient has been followed up with coronary artery disease, heart failure, and diabetes mellitus type 2 diagnoses, and the diagnosis of ST elevation myocardial infarction (NONSTEMI) was followed up with coronary intensive care unit. 2 coronary artery bypass grafting (CABG) were performed before and subsequently was percutaneous intervention was applied to the circumflex artery (CX), followed by 2 (CX) and percutaneous interventions was applied to the

left coronary artery (LMCA). On echocardiography; left ventricular ejection fraction (EF) was assessed as 25%. The laboratory values of the patient were pathologically determined as blood glucose 204 mg / dl, troponin 372 and haemoglobin 10.4 gr/dl.

The patient had to go to the hospital in the last year, 11 times with decompensated heart failure and persistent angina pectoris. In the recent coronary angiography of the patient; LMCA 90%; CX proximal 99%; 99% proximal left anterior descending artery (LAD); 99% in the right coronary artery 99% narrow artery and diffuse atherosclerosis in all coronaries were observed and the patient's saphenous grafts were found to be occluded (Figure 1). The patient underwent a LMCA bifurcation and further attempts to be realized by cardiology team were considered risky. Medical treatment of the patient was as follows; ramipril 2.5mg, metoprolol 50mg, spiro lactone 25mg, ticagrelor 90mg, acetylsalicylic acid 100mg, furosemide 40mg, ranolozin 375mg and trimatezadin 35mg. The patient was evaluated in cardiology and algology clinic for pain control upon since reattemptive invasive intervention wasn't considered by the cardiology-cardiovascular council. Because the patient had terminal period heart failure, stellate ganglion blockade was decided.

The patient was treated with 1 mg intravenous midazolam + 50 mcg fentanyl, after 6, vertebra-level scopi coincidence with contrast material, ganglion blockade with left stellate ganglion 40 mg bupivacain + 8 mg dexamethasone (Figure 2). The angina complaint of the patient, who had no complication after the procedure, disappeared. The patient died due to decompensated heart failure 3 days after the procedure.

Discussion

It is thought that there are special nociceptors in the heart. Heart-related pains are common and moderate. In contrast to pain severity, nausea, vomiting due to neuroendocrine stress response, blood pressure and heart rate changes can be accompanied by the actual visceral pain as well as the reflected pain spreading to the upper part of the neck, shoulder, chest and abdominal wall can be seen.

Angina pectoris refractory to medical therapy, an-

Figure 1. (a, b) LMCA 90%; CX proximal 99%; 99% stenosis at LAD proximal. (c) 99% stenosis in right coronary artery. (d) Post LMCA intervention.

gioplasty and coronary bypass surgery cannot be controlled with a combination of, angina due to the fact that coronary insufficiency is a chronic condition that is characterized by the presence of angina.^[1] The patient should be evaluated by the heart team, where the ischemic origin of the angina and the revascularization cannot be applied. The majority of patients with ischemic heart disease can be treated with medication and revascularization procedures. While the development of cardiovascular care increases the number of patients with end-stage coronary artery and refractory angina also increases. However, there is still no standard approach to refractory angina pectoris. In these patients, quality of life has deteriorated due to repetitive and continuous pain, poor general health status, psychological distress and limited activity.^[2] In order to exclude the devel-

opment of a new disease that can be treated with revascularization, patients are advised to have regular angiography. Our patient was frequently admitted to emergency room with recurrent chest pains and had a severe activity limitation.

In addition to medical treatment in patients with chronic refractory angina pectoris, additional treatment methods include laser revascularization, transmyocardial laser revascularization, angiogenesis, growth factor and gene therapy.^[3] In addition, the specialists of algology or anaesthesiology are involved in the treatment with thoracic epidural anaesthesia for palliative purposes, unilateral left stellate ganglion blockade and spinal cord stimulator.^[3] It appears that the unilateral left stellar ganglion blockade is not a protocol for the use of cardiac pathologies. In addition to persistent angina patients with unilateral left stellar ganglion blockade, there are case reports in the literature used in the treatment of long QT syndrome and refractory ventricular tachycardia (VT storm).^[4,5] One-sided stellat ganglion blockage can only be done in the form of a block with local anaesthetic agent; local anaesthetic agent +6% phenol mixtures can be done applied. After diagnostic block, stellar ganglia radiofrequency thermo coagulation can also be applied.

Cervicotoracic (stellate) block is an attempt to diagnose and treat the symptoms of the head, neck, upper chest and upper extremities of complex regional pain syndromes (CRPS), sympathetic pain and symptoms.^[6] Although the technique used widely during stellate ganglionic blockade is anterior paratracheal technique, lateral and posterior approaches are also defined.^[6]

SGB can be applied with two finger methods from C6 (Chassignac's tubercle) and C7 levels.^[6] It provides blockages from all cervical ganglions and upper thoracic ganglions to T5 ganglions depending on the drug volume. At the end of the operation, pocsis, myositis, enthaltymia, nasal deconjesion and anhrizia in the neck and Horner's syndrome occurs at the same side.^[6,7] Because it is easier to palpate the SGB, as it is more distant from the pleura, and because the risk of vertebral artery puncture is lower, it is preferred to do it at C6 level.^[6] In this study, we aimed to investigate the relationship between the severity of

coronary artery disease and the risk of coronary artery disease in patients with coronary artery disease (CAD). In our case, the anterior paratracheal stellate ganglion blockade was performed with two fingers and the complication was not developed.

In a prospective study they performed, Saraste et al., found changes in myocardial perfusion reserve in patients who underwent SCS treatment for refractory angina pectoris.^[8] Patients over 80 years of age who were admitted as contraceptive for SCS treatment, those with ventricular injection fraction <40%, acute coronary syndrome, decompensated heart failure, VF, ventricular tachycardia continuing for 3 months, severe asthma, 2nd and 3rd degree AV block patients were not included in the study.^[9] In addition to being EF: 25% of our patient, recent heart failure is present, since life expectancy of less than 1 year assessed by the heart team we thought it would not be suitable for SCS treatment. However, because the aneurysm was severe, we thought that thoracic epidural anaesthesia or unilateral left stellate ganglion blockade could be applied. We considered that partial injection of thoracic epidural anaesthesia should be performed, the epidural catheter should be kept in place, but there is no catheter in the left unilateral ganglia block, and the number of invasive procedures would provide a smaller number of long-term blockages. In our patient, we provided unilateral left stellate ganglion blockade without complications.

Result

Cardiology, anaesthesiology and algology experts should keep in mind that unilateral left stellate ganglion blockade is a part of palliative care in patients with chronic refractory angina during the last stage of heart failure.
