An emergency laparotomy for damage control surgery with perihepatic packing was decided (Fig. 1f). Bleeding persisted after selective hepatic embolization, and a right hepatic lobectomy was performed. Bridging therapy with cangrelor was applied using thromboelastography with platelets mapping for drug titration (TEG 6s Haemonetics®) (Fig. 1g).

The lobectomy was successful (Fig. 1h, 1i), and the patient had a complete full recovery with normalization of the left ventricular function. She returned to work 1 month later in good health.

Antithrombotics and anticoagulants may exacerbate an existing liver injury into a large intrahepatic hematoma, a very rare flip side of successful resuscitation. The otherwise fatal complication, in a precarious ischemic–hemorrhagic balance, was successfully managed thanks to a perioperative bridge therapy with cangrelor titrated according to thromboelastography/platelet function assay and a coordinated multidisciplinary team approach.

Bilateral coronary artery–pulmonary artery fistulas with a giant coronary aneurysm

A 61-year-old female patient visited the local hospital 1 month before due to lumbar disc herniation and sciatic nerve compression. After treatment with “mannitol and dexamethasone” by intravenous infusion, she had dizziness, palpitations, flushing, and sweating, among other symptoms. Her blood pressure was 150/87 mm Hg, and the abovementioned symptoms lasted for about half an hour. After 3 days of infusion, the patient still experienced dizziness, palpitations, and sweating; her symptoms relieved about half an hour after administering nitroglycerin. These symptoms often occurred between 7 and 9 a.m. and had nothing to do with the patient’s daily activities or eating habits. The patient was referred to our hospital for further treatment. The electrocardiogram was normal, and transthoracic color Doppler echocardiography (TTDE) showed left coronary artery–pulmonary artery fistula and left coronary artery aneurysm dilation (Fig. 1a and 1b). Coronary angiography showed bilateral coronary artery fistula and anterior descending giant coronary artery (Fig. 1c and 1d). Coronary computed tomography angiography (CCTA) showed bilateral coronary artery–pulmonary artery fistulas with anterior descending coronary artery aneurysm (Fig. 2a–2d, Video 1). Coronary angiography showed bilateral coronary artery fistula and anterior descending giant coronary aneurysm (Fig. 1c and 1d, Video 1). Coronary computed tomography angiography (CCTA) showed bilateral coronary artery–pulmonary artery fistulas with anterior descending coronary artery aneurysm (Fig. 2a–2d, Video 2); thus, the patient underwent surgery. During the surgery, the inlet and outlet of the left and right coronary artery–pulmonary artery fistulas were fully dissociated and ligated using the lateral wall forceps to clamp the aneurysm; then, we cut open the coronary aneurysm and found the thrombosis. Finally, we closed the aneurysm stump by suture. Pathological examination was performed after aneurysm surgery (Fig. 2e). We noted that the coronary artery was not clipped during the surgery. CCTA was performed again 1 week after surgery, which revealed that the coronary artery–pulmonary artery fistula and coronary artery aneurysm had disappeared (Fig. 2f, 2g, 2h; Video 3). Thus, the patient was discharged quickly, and no further complications occurred.

Video 1. Coronary angiography revealing a right coronary artery fistula and a large anterior descending coronary artery aneurysm

Video 2. Preoperative CT image of the bilateral coronary artery–pulmonary artery fistula and giant coronary aneurysm

Figure 2. Volume reconstruction (VR) showing that the left anterior descending coronary artery and the right coronary artery each emit a blood vessel, which is upwardly distorted and traveled. The distal end is connected with the left anterior wall of the main pulmonary artery (a) and (b); thin and thick arrows indicate the coronary artery fistula and aneurysm, respectively; multiplane recombination (MPR) shows a fistula aneurysm thrombosis of 53 mm diameter (c) and (d); thin and thick arrows indicate coronary artery fistula and aneurysm, respectively. Coronary computed tomography angiography shows that the coronary artery–pulmonary artery fistula and giant aneurysm disappear after surgery, VR (e) and (f), CPR (curved planar reconstruction) (h). Pathological examination shows disappearance of the middle wall of the coronary artery aneurysm, with local secondary thrombosis and atherosclerosis (g)

Video 3. Postoperative CT findings of the bilateral coronary artery–pulmonary artery fistula and giant coronary aneurysm
