severe mitral regurgitation and a suspicion of cardiac mass, trans-esophageal echocardiography (TEE) was performed. TEE demonstrated severe mitral regurgitation and a huge caseous calcification of the mitral annulus mimicking a mass in the posterior mitral annulus (Fig. 2, Video 3. See corresponding video/movie images at www.anakarder.com). We decided to place a dual-chamber pacemaker due to atrioventricular block. After dual-chamber pacemaker implantation mitral regurgitation decreased and on transthoracic echocardiographic examination mild mitral regurgitation was seen (Fig. 3, Video 4. See corresponding video/movie images at www.anakarder.com). The symptoms resolved and the patient was discharged. We conclude that caseous calcification of the mitral annulus should be considered a cause not only in the background MR but also in the differential diagnosis of cardiac masses and conduction system disease.

Video 3. TEE demonstrates caseous calcification of the mitral annulus mimicking mass and severe mitral regurgitation

Video 4. View of mild mitral regurgitation after a dual-chamber pacemaker placement

Enfektif endokardite bağlı gelişen aort kapak vejetasyonunun ve anteriör mitral kapak perforasyonunun üç boyutlu transözefajiyal ekokardiyografi ile değerlendirilmesi

Complicated left-sided native valve infective endocarditis remains a serious disease with significant morbidity and mortality. Mitral perforations are rare complications of destructive endocarditis. A 50-year-old woman has applied for fever and shortness of breath for 3 months. Electrocardiography showed a sinus tachycardia. Two-dimensional transesophageal echocardiography demonstrated severe mitral and aortic regurgitation. Two-dimensional transesophageal echocardiography (2D-TEE) revealed mitral valve perforation and aortic valve vegetation (Fig.1A and Video 1A. See corresponding video/movie images at www.anakarder.com), also severe aortic and mitral regurgitation because of destructive endocarditis (Fig. 1B and Video 1B. See corresponding video/movie images at www.anakarder.com). To better define this pathology, we performed three dimensional transesophageal echocardiography (3D-TEE). 3D zoom modality TEE displayed mitral valve perforation at A2 scallop (Fig.1C and Video 1C. See corresponding video/movie images at www.anakarder.com) and vegetation at the aortic valve (Fig. 1D). Infective endocarditis is a life-threatening disease still associated with a high mortality rate despite recent advances in diagnostic imaging, antimicrobial, and surgical therapies. Aortic valve is primarily affected in the left-sided endocarditis, and then mitral anterior...
leaflet is involved due to aortic regurgitation. Mitral anterior leaflet endocarditis may cause aneurysmal formation and then it can lead to mitral perforation. The sensitivity of TTE ranges from 40 to 63% while that of TEE ranges from 90 to 100% for endocarditis. Furthermore, newer imaging modalities such as 3D TEE can provide a more detailed evaluation especially for complications of destructive endocarditis.

**Prosthetic mitral valve obstruction:** diagnosis with real-time three-dimensional transesophageal echocardiography

Mitral protez kapak disfonksiyonu: Gerçek zamanlı 3 boyutlu transözefageal ekokardiografik görüntüleme

Prosthetic valve obstruction is a fatal complication of mechanical valve replacement surgery which develops due to thrombosis or pannus formation. A 62-year-old-man who underwent prosthetic mitral valve (PMV) replacement four months ago, was admitted to our hospital with acute heart failure. The INR was 10 on presentation. However, two months before his admission, the INR value was 1.5. On transthoracic echocardiography (TTE) mean diastolic transmitral gradient was 13 mmHg and effective regurgitant orifice area 1 cm². Based on TTE image, we suspected restricted motion of the posterior leaflet of prosthetic mitral valve (Fig. 1). Two-dimensional (2-D) transesophageal echocardiography (TEE) revealed dysfunction of posterior leaflet (Video 1. See corresponding video/movie images at www.anakarder.com). Cine fluoroscopy confirmed malfunction of the mitral posterior leaflet (Video 2. See corresponding video/movie images at www.anakarder.com). Real time three dimensional (3D) TEE (iE 33 ultrasound, Philips Medical Sytems) demonstrated restricted motion of posterior leaflet (Video 3. See corresponding video/movie images at www.anakarder.com). There was no evidence of thrombus on the PMV, in 3D TEE examination. 3D images demonstrated a pannus like mass extending to both the atrial and ventricular sides of the prosthetic valve. Because of his critical condition, urgent operation was offered, however immediately after TEE examination his clinical status deteriorated and he died. In this case, real time 3-D TEE has been presented as a sufficient approach, providing accurate assessment of early prosthetic valve dysfunction.
