ABSTRACT

Introduction: Obesity and its comorbidities are among the primary challenges faced by health systems globally. Obesity is rapidly becoming a problem in Turkey, as well. Real cost of obesity surgery differs from country to country, largely due to differences in costs of health care services, medical devices, and medicines. The objective of this study was to determine operational cost of obesity surgery in Turkey.

Materials and Methods: Expert panel was primary source of data in the study. Following literature review of costs of obesity surgery, questionnaire was designed for expert panel. Form was sent to the experts in advance of panel discussion held to reach consensus. After consensus-building phase, cost of surgical treatment of obesity was estimated based on public reimbursement and auction price.

Results: Laparoscopic by-pass surgery had highest cost among obesity surgeries in both operational and postoperative costs, while laparoscopic sleeve operation had highest preoperative cost. Package payment included all costs and services from preoperative period through 15 days after operation. Based on analysis, package reimbursement prices were below actual costs for all surgical methods.

Conclusion: Social Security Institution reimburses cost of obesity surgery at fixed amount of 4500 TL, 3100 TL, and 2250 TL for by-pass, sleeve, and banding surgeries, respectively. This fixed amount includes preoperative, operative, and postoperative periods. It was observed that fixed amount provided is lower than real cost of the practice of obesity surgery. As a result, hospital management may avoid performing obesity surgery or reduce the quality of surgical treatment to reduce losses. Decision makers may need to evaluate results of the study to understand accurate picture and take action in order to improve obesity surgery reimbursement.

Keywords: Cost of obesity surgery; obesity surgery.
**Introduction**

Health Organization (WHO) defined obesity as an abnormal or excessive fat accumulation that may impair health. [1] Obesity is a growing health problem in all countries including Turkey. Comorbidities of obesity have crucial impact on the burden of the illness. Death risk of an obese person may increase 30% for every 15 additional kilogram of weight. [2] It was concluded in the 2003 Turkey Burden of Disease Study (TBDS) that 26,006 and 31,136 deaths for males and females, respectively, may be prevented decreasing the prevalence of obesity. [3] 30.3% (20.5% of males, 41% of female) of the Turkish population was reported obese in a research. [4]

Behavior change, diet, exercise, medicines, and surgery are the reported treatment options for obesity. The surgery named “bariatric/obesity surgery” was reported as a clinically and cost-effective application for moderately to severely obese people compared to other treatment options. [5–28]

The real cost of obesity surgery differs from country to country mainly due to differences in the costs of health care services, medical devices and medicines. However, the reimbursement of obesity surgery is needed to be correlated with the real cost; it may be lower or higher than the real cost. Social Security Institution (SGK), the largest health care payer organization in Turkey, reimburses the operation of obesity surgery with a fixed amount without considering the severity of patients or comorbidities using the Supplement-2C in the Health Application Statement (SUT Ek-2C) (http://www.sgk.gov.tr). It was reported that the operational cost of sleeve gastrectomy was 8,930 TL for a hospital from the Turkish Public Hospital Union Hospitals (TKHK). [29] However, as the result is based on a cost analysis of a single hospital, the study does not represent Turkey. The objective of this study is to estimate the real operational cost of obesity surgery in Turkey in order to understand the possible differences between reimbursement price and real costs.

**Materials and Methods**

Delphi Panel Technique was used to determine the operational cost of obesity. In the literature, Delphi Panel Technique is described as a valuable scientific method where the topic is discussed with local experts as consultants to ensure consensus. Seven experts from different institutes have participated in the Delphi panels. After reaching a consensus in the Delphi panel, an operational cost of obes-

sity surgery calculation model has been developed for the study. Prices of health care services and pharmaceuticals have been reached from SGK (http://www.sgk.gov.tr) to estimate the cost of health care services for the year 2012. The average price of medical devices has been obtained from Public Procurement Authority (KIK) (http://www.ihale.gov.tr) to calculate the cost of medical devices for the same year. The exchange rate for Turkish Liras (TL) to United States Dollars (US $) was used as 1.84 for the year 2012. Pre-operation, operation and post operation costs covered by reimbursement payment were calculated for laparoscopic gastric by-pass, sleeve gastrectomy and banding operations. Surgeon fee was not included in the calculation due to the differences in the fees of the surgeons set by the hospitals.

**Results**

Table 1 presents the prices of health care services, medical devices and pharmaceuticals used in each operation based on the results of the Delphi panel for pre-operation, operation and post operation. Pre-operation costs are US$ 155 for laparoscopic banding, US$ 478 for laparoscopic sleeve gastrectomy and US$ 202 for laparoscopic gastric by-pass operations. Pre-operative, operative and post operative costs were calculated as US$ 1766, US$ 3.029 and US$ 3721 for laparoscopic banding, laparoscopic sleeve gastrecto-

my and laparoscopic gastric by-pass, respectively in Table 2. Pre-operative, operative and post operative costs were calculated as US$ 478, US$ 3.029 and US$ 142 for sleeve gastrectomy, respectively. The comparison of the cost of bariatric surgical procedures and SSI package prices from Delphi panel are presented in Table 3. In Table 3, the price differences are US$ 1659 for gastric bypass, US$ 1975 sleeve gastrectomy and US$ 749 for banding. The percentage of differences form gastric bypass, sleeve and banding are 68%, 117% and 61%, respectively.

**Discussion**

The practice of obesity surgery is an increasing trend in the morbid obese people. Laparoscopic procedures serve less mortality and morbidity for obesity surgery.[30] Quality of life may improve with weight loss after surgery. On the other hand, it was reported that obesity surgery is more costly than non-surgical treatment options.[31–35] In spite of the increased cost, obesity surgery serves better clinical outcomes than non-surgical treatment options and is also reported cost effective.[16]

SGK reimburses the obesity surgery with a fixed amount of 4500, 3100 and 2250 Turkish liras for by-pass, sleeve and banding surgeries, respectively. This fixed amount covers pre-operative, operative and post-operative period. It was shown that the fixed amount is lower than

the real cost of obesity surgery. The highest reimbursement and real cost are reported for by-pass gastrectomy. However, major difference was calculated for sleeve gastrectomy with 117%. In other words, should a hospital management allow to perform sleeve gastrectomy, hospital budget suffers more loss than the reimbursement amount. Less loss and percentage of deficit may be obtained by banding operation.

As stated earlier, the operational cost of sleeve gastrectomy was found to be 8,930 Turkish liras for a hospital from the Turkish Public Hospital Union Hospitals (TKHK). However, the reported result of TKHK is above the results of the study; both studies show that the reimbursement amount of SGK for obesity surgery is lower than the real cost.

This study has some limitations. The study was not based on real patient claims data, but on the opinions of 7 experts from different institutions. In addition, the cost of health care services was acquired as SGK price, not real cost to the hospital budgets due to lack of information on hospital databases.

Conclusion

There are two different published guidelines for obesity treatment in Turkey; however, recommendations are similar to the literature. Obesity surgery was recommended for severely medical patients with BMI >40 kg/m² or BMI=35–39.9 kg/m² together with a severe co-morbidity in the “National Obesity Prevention and Treatment Guideline” by “Obesity Research Association of Turkey” and the “Turkish Society of Endocrinology and Metabolism” in “Obesity Treatment Guideline and Lifestyle Advices”. However, the payment by SGK is only offered for patients with BMI >40 kg/m². Present study reveals that the reimbursement of the practice of obesity surgery was lower than the real cost, meaning the budget of a hospital to be influenced negatively if the surgery was allowed. As a result, hospital managements can avoid performing obesity surgery or reduce the quality of the surgical treatment by lowering the possible loss. Patients needing obesity surgery may be influenced by these possibilities. They may not get treated or get poorly treated with low quality service leading to an increase in the possible morbidity and mortality rate. Decision makers may need to evaluate the results of the study to understand the real picture and take action in order to improve the reimbursement of obesity surgery.
