Neodymium is a chemical element that was discovered in 1885. This element (atomic number 60) has a silvery-white metallic color and belongs to the group of lanthanides, which is a subgroup of rare earth elements (atomic numbers 57–71) in the periodic table and rapidly oxidizes in air. Lanthanides play important roles in new technological developments, such as wind turbines, electronic hybrid vehicles, and in the defense industry.

In nature, neodymium does not exist in metallic or in mixed forms with other lanthanides but is refined for general use and has been mined in the USA, Brazil, India, Australia, Sri Lanka, and predominantly in China.

Neodymium-iron-boron magnets were developed by General Motors and Hitachi in the 1980s. Because it provides high magnetic force even in lesser amounts, it has been increasingly given a more prominent role in the manufacture of strong permanent magnets made up of rare earth elements. In the field of information technology, neodymium magnets are particularly used in hard disc drives, mobile phones, video and audio systems of television [1].

Neodymium magnets are also commonly used in magnetic separators, filters, ionizers, in production of on–off buttons, safety sector and security systems. Grease filter producers use neodymium magnets in metal separators to more effectively filter out iron powder in oil. Additionally, they are beneficial in covering machines, cars with awning and in the production of magnetic tool belts. They are also used in jewelry clips, identification badges and in the production of baby strollers that are attached to carriers via magnets.

The health sector is another field where neodymium magnets are incorporated in medical devices for example in magnetic resonance imaging devices to diagnose and treat chronic pain syndrome, arthritis, wound healing, insomnia, headache, and several other diseases due to their
ability to generate a static magnetic field. An increase in
their usage has been observed over the last decade [2].
These magnets are thought to have a curing effect and are
therefore sometimes called “magic magnets”.

NASA uses neodymium magnets to maintain the
muscular tonus of astronauts during space flights [2].
Neodymium magnets have push–pull forces and have
been used as a motion-generating device in orthodontic
treatments; molar distillation, and palatal expansion [3, 4].

Static magnetic field has been reported to stimulate
bone formation via osteoblastic differentiation or activa-
tion [5, 6].

The amount of neodymium magnets used in all these
areas has risen from 1 ton to 60,000 tons between 1983
and 2007. Since 1990, China has been predominant in
the mining of rare earth elements. The mining of rare ele-
ments has various environmental impacts because of the
low concentration of these substances; therefore, many
countries have stopped the mining of rare elements and
almost all countries depend on imports from China [1].

Effects of neodymium magnets on health
and medical usage

Cardiovascular system

In a study conducted in 2004, laser doppler was reported
to significantly reduce blood flow and skin blood perfu-
sion (SBF) in the 2nd and 4th fingers of the non-dominant
hands of both poles of the neodymium magnet [7].

Another study indicated that neodymium magnetic
fields increases the nail bed microcirculation although
this study conflicted with other studies [8].

The flow of red blood cells in the skeletal muscle capil-
laries exposed to strong static magnetic fields has been re-
ported to be reduced [9]. Intra tumoral microcirculation
is characterized by tortuous micro vessels with chaotic
structures and unstable irregular blood flow. A study has
reported a decrease in the blood stream and blood vessel
density in tumors that were treated using static magnetic
fields. In the same study, it was shown that in non-tu-
morel skeletal muscles exposed to static magnetic fields,
platelet activation and adhesion increased [9]. The mag-
netic field generated by neodymium magnets is thought
to increase microcirculation but the effects on this are
not clearly known.

In a study, a special device was surgically placed on
the backs of laboratory mice. Neodymium magnets were
attached to the device in one group, and non-magnetic,
equal-sized, and same-weight platters were attached in
the other group. The arteriole and venule diameters of
the mice exposed to static magnetic field generated by
neodymium magnets were demonstrated to be consider-
ably reduced [10].

Another study, conducted in 2015, where the portal
veins of dogs were cut and reconstructed, the anastomo-
sis in one group was performed using traditional manual
sutures and that in the other group was by covering it
with rings comprising of neodymium magnets. In the lat-
ter, the recovery lasted for a considerably short time and
the intima was smoother and regularly formed than in
the former [11].

Bipolar ablation catheters, unipolar ablation catheters
and bipolar catheters with magnets attached to them
have been tried in thick and tight tissues where it is hard
to create a full-thickness lesion like in the left ventricu-
lar wall. Both the transmural passage and the thickness
of the lesion formed by the magnetized bipolar catheter
were found to be higher than others [12].

Neural system

Magnets can be used to generate magnetic fields in neural
electrical activity research. The effect of magnetic fields
created using neodymium magnets on neural damage
was examined in a study where they were applied on 17
healthy volunteers for 2 hours. Neuron specific enolase
which is the determinant of neuronal damage and S100
blood levels were studied, the test conducted to measure
mental ability revealed that the parameters tested on the
17 volunteers were not affected by the magnetic fields
and to generate a magnetic field with neodymium mag-
nets seemed to be safe on these parameters [13].

Recurrent transcranial magnetic stimulation (rTMS)
is an approved and effective treatment method for major
depression. Synchronized TMS (sTMS), which is the
modified form of rTMS, has also been tried for the treat-
ment of the same. A study conducted in 2014 revealed
that while the occurrence rate of patients who suffered
from major depression and treated with sTMS declined
by 48%, it declined by 19% in the control group, and this
difference was statistically significant. Neodymium mag-
nets are used in TMS to generate magnetic fields and In
contrast to electroconvulsive treatment for major depres-
sion, TMS does not require anesthesia [14]. Further an-
other study conducted in 2015 revealed the use of sTMS
to be effective in the treatment of major depression [15].

Placing of magnets on upper and lower eyelids in the
treatment of lagophthalmos has obtained successful results [16].

Alternative treatment methods including magnetic therapy have been researched on menopause vasomotor symptoms and it has been found that they are not effective in the treatment of these symptoms [17].

In another study, to ensure glottis aperture in bilateral vocal cord paralysis, magnets were placed ex vivo in sheep larynx had the gap widened. The device provide a suitable glottis aperture that benefit from magnets and this may be used in the future [18].

**Skeleton, muscle, and joints system**

The effect of neodymium magnet implants placed in rabbit tibia and that of non-magnetic implants on bone tissue have been compared. Magnetic implants reinforced both medulla and cortex around the bone tissue and the increase in the medulla was statistically significant [19].

In another study conducted using a trabecular damaged rabbit model, a magnetic scaffold was placed in the damaged area of the distal femoral epiphysis and cylindrical neodymium magnets (NdFeB) were placed in a nearby area, the interaction observed. At the end of the experiment, it was found that NdFeB protects against micro movements by keeping the magnetic scaffold constant and it is important in maintaining regular tissue regeneration [20].

In a randomized double blind placebo controlled research, the curing effect of neodymium magnets on osteoarthritis symptoms was investigated; participants were made to try on four types of wrist straps. During the comparison, magnetic neodymium wrist straps were used as an experimental device, and low magnified, demagnetized, and coppery wrist straps were used as control devices. The WOMAC Osteoarthritis Index, McGill Pain Questionnaire-Pain Rating Index (PRI), visual analog scale, and medicine intake were evaluated. Among these scales, only PRI subscales revealed statistically significant difference. Therapeutic benefits of wrist straps have attributable placebo effect. These devices have no major adverse effects therefore can be used for placebo effect [21].

In another study, the difficulty of forming a control group where magnetic bracelets tested, addressed that giving a weakly effective wristband to the control group might not be effective in relieving pain in arthritis as the participant could test the strength of the wrist [22].

In a research in which the role of static magnetic field in carpal tunnel treatment was researched on, the effects of two different magnetic field levels on the median nerve were evaluated. In a randomized double blind placebo controlled research, 12-week long observation was performed after a 6-week long interference. Participants who were diagnosed with carpal tunnel syndrome using electrophysiological tests wore neodymium magnets and non-magnetic disks all night long. Boston Carpal Tunnel Questionnaire, symptom severity score (SSS), function severity score (FSS), and four parameters measuring the median neural activity were used. These parameters included sensory distal latency, sensory nerve action potential amplitude, motor distal latency, and compound motor action potential amplitude. Among the groups, no significant difference was found in SSS and FSS median nerve conduction. A recovery in symptoms was observed in a 6-week period for SSS and FSS in both groups. The change of symptoms in both magnetic and non-magnetic disc groups occurred in the same direction and size [23].

In two systematic reviews conducted in 2012 in which magnetic wristbands and several other alternative treatments were examined for arthritis, by citing the lack of enough research on the subject, it was concluded that there was no consistent evidence that it was effective for rheumatoid arthritis and osteoarthritis treatment [24, 25].

**Gastrointestinal system**

In a study conducted in 2012, neodymium magnets were used to fix endoscopically determined colon tumors. During the laparoscopic surgery performed without tools such as fluoroscopy or ultrasonography, the magnets were used for an easy access to the tumor. The intra-operative localization of marked lesions was successful in 27 (96%) of 28 patients [27].

In an animal study, ring-shaped magnets were endoscopically used for magnetic compression anastomosis (magnamosis), being placed opposite to each other in the targeted areas [28, 29]. Magnets have also been surgically used in humans; unwanted tissues in the operative area were safely removed using magnetic forceps in 44 laparoscopic operations, including cholecystectomy, gastrojejunostomy, and splenectomy, performed on pediatric patients between 2009 and 2011 [30].

Previous studies on swallowed magnets have documented
life-threatening injuries including, fistula and perforation, particularly in children. In two separate studies comparing the number and size of magnets swallowed by children in 2002–2009 and 2010–2012, there was an increase in the number of cases involving more than one magnet and a decrease in the size of the magnet swallowed, but all cases required surgical intervention. This result was attributed to an increase in the availability of magnets to children in everyday life [31]. These findings suggest that the use of magnets rather than safety pins can be particularly harmful for children. North Atlantic American Society for Pediatric Gastroenterology, Hepatology, and Nutrition advocated for the ban on the sale of strong magnets including neodymium, but they stated in 2014 that these efforts were not effective enough [32].

Magnet related injuries
In a case report published in 2015 that led to the initiation of measures governing the use of magnets at the workplace, it was pointed out that a 52-year-old man was injured while trying to generate electricity for experimental purposes using a device containing neodymium magnets. The magnet crashed into pieces injuring his face. The report further discussed the difficulty of operating with strong magnets using traditional tools and the possible damages of uncontrolled movements caused by such tools. Accordingly, it was stated that there is also a need for medical equipment that are insensitive to magnetic effects [33].

Orientation of iron-containing nanoparticles by magnets and their use in pharmacotherapy
Currently, magnetic iron oxide nanoparticles are used in several biomedical and neurobiological operations such as those performed for the monitoring and treatment of tumors.

A study reported that the attachment of oxide nanoparticles to the astrocytic membrane and their entrance into the cells becomes easier by virtue of the magnetic field generated by neodymium magnets laid under the astrocyte cells in the brain [34].

Human stem cells in serum-free medium, to which an amount of magnetic nanoparticles containing iron (0.043 mg/ml) was added in a nontoxic level, were used along with neodymium magnets and observed on a daily basis. No effect on stem cell prepotency and proliferation was recorded was reported in this study [35].

In a study conducted on pigs in 2014, vascular stents were rendered magnetic by means of neodymium magnets and, thus, ensured to hold to endothelium cells that were supported with iron particles. This may lead to an important development in stent-related procedures because the acceleration of endothelialization would reduce the risk of thrombosis [36].

An animal study published in 2012 had the orientation of stem cells containing iron particles to the targeted area in the retina again ensured with neodymium magnets. This appeared to be particularly important in the treatment of age-related macular degeneration and retinitis pigmentosa [37].

Nanoparticles loaded with cytotoxic chemotherapeutic agents can be oriented toward tumors. In tumor areas, capillary permeability increases and particles that cannot intercellularly travel elsewhere can pass into the tumor. This passage of nanoparticles can be reinforced through orientation by magnets [38].

In an experiment on aneurysm closure, magnets placed on the outer body of experimental rabbits were used to direct magnetic micro particles in the circulation toward the area for at least 30 minutes. Although aneurysmal recanalization was observed 12 weeks later during follow-up, this was an important study for possible new modalities in the treatment of aneurysms [39].

Another study conducted in 2014 showed that sperms exposed to magnetic field were more enduring [40].

Use of magnets in dentistry
Magnets have also been used in orthodontic operations. The outward movement of the buried tooth root in cases of dental fracture can be achieved using magnets in 9–12 weeks. The root reaching out can then be reformed by methods such as porcelain coating [41]. Neodymium magnets are used with coatings as they are not resistant to corrosion and gradual loss of strength [42].

Conclusion
Electronic devices are being increasingly used in our lives. Fossil fuels are being replaced by renewable energies, a field that increasingly uses rare earth elements. These elements are used in electric cars and wind turbines. Although procurement challenges and high prices lead producers to seek alternatives, rare earth elements are still being used in numerous technology and Because of their demand, the health effects of these powerful magnets must be addressed along with their environmental impacts.
In this review, the history, definition, and properties of rare earth magnets were briefly explained. Additionally, basing on the results roughly examined from the studies carried out so far, we concluded that there are effects of magnets, especially neodymium magnets, on body systems, tissues, organs, diseases, and treatments. Although they have been used in various diagnostic devices in the health sector and as therapeutic tools, magnets are potentially harmful to the body and pose increased risk of accident. Despite insufficient studies conducted on the effects of neodymium magnets, they appear to have a great potential for both diagnostic and therapeutic procedures.
