ABSTRACT
OBJECTIVE: In this study, the effect of mesalazine was studied on TNF alpha, IL-1 beta, IL-6, and C-reactive protein (CRP) levels and inflammatory changes in rat lungs with experimental peritonitis.

METHODS: In total, 24 male Sprague–Dawley rats weighing 250–280 g were used in the study. The rats were divided into three groups based on no irrigation or irrigation with isotonic solution or mesalazine. Secondary peritonitis was generated by cecum penetrations. Group I: no irrigation was given after the development of peritonitis; Group II: irrigation was performed using isotonic solution 24 h after the development of peritonitis; Group III: irrigation was performed using mesalazine 24 h after the development of peritonitis. Blood samples were taken in the 48th hour for measuring TNF alpha, IL-1 beta, IL-6, and CRP levels. Lung tissue samples were taken for examining the effect of mesalazine in the development of systemic sepsis.

RESULTS: TNF alpha, IL-1 beta, and CRP levels were significantly low in Group III than in the other groups (p<0.005). In the histologic examination, leucocyte infiltration in the lung was found low in Group III.

CONCLUSION: TNF alpha, IL-1 beta, and CRP levels and leucocyte infiltration in the lung were found to be low in rats that were administered peritoneal irrigation using mesalazine after the development of secondary peritonitis. Peritoneal irrigation using mesalazine may be useful in patients requiring surgery due to secondary peritonitis.

Keywords: Peritonitis; TNF alpha; IL-1 beta; IL-6; mesalazine.

Sepsis is a serious pathology with significant morbidity and mortality [1]. Some proinflammatory mediators indirectly cause sepsis as a response against exposure to microbial products. Cytokine response is associated with morbidity and mortality in sepsis [2, 3]. Microbial products include liposaccharides (endotoxins or lipopolysaccharides) produced by gram-negative microorganisms, peptidoglycans and teichoic acids produced by gram-positive microorganisms, cell-wall components and many others produced by fungi and yeasts.

Secondary peritonitis is a common morbidity that requires surgical intervention. Gastrointestinal system-related intra-abdominal contamination initiates the cytokine synthesis. Cytokines TNFα and IL-1β lead the pathogenesis of sepsis. These cytokines increase in the first 4 h after the development of sepsis. They reach the highest level in the 24th hour. C-reactive protein (CRP) is an acute-phase reactant, and CRP levels increase in sepsis.

Mesalazine or 5-aminosalicylic acid (5-ASA) is an anti-inflammatory and antioxidant drug that has been
used in treatment of inflammatory bowel diseases for approximately 50 years [4, 5]. 5-ASA is a small hydrophilic organic acid and is well absorbed from the intestines. It is rapidly transformed to N-acetyl in the intestinal epithelium and liver, and the inactive molecule N-acetyl-5-ASA is generated. Some parts of the inactive metabolite are secreted back to the lumen and removed from the body by feces. Some parts of 5-ASA are metabolized in the liver and extracted by the kidney. However, the clinical effect of 5-ASA is not associated with systemic absorption and redistribution on target organs; its topical effect is observed in the colon. There are various views on the effect mechanisms of 5-ASA complexes. It was stated that 5-ASA complexes inhibit IL-1 and IL-2 synthesis in the inflammatory period. It was also proved that they inhibit TNF-α synthesis [6].

The aim of the present study was to investigate the effect of intra-abdominally administered mesalazine on cytokines (TNF-α, IL-1β, and IL-6) and on the level of acute-phase reactant CRP during sepsis due to secondary peritonitis.

**MATERIALS AND METHODS**

**Animal study**

The study was conducted at the Institute of Experimental Medicine, Istanbul Faculty of Medicine, Istanbul University. The study protocol was approved by the Animal Care Ethics Committee. All procedures were conducted in accordance with the ethics guidelines for the treatment and welfare of experimental animals by the Istanbul Faculty of Medicine, Istanbul University, and Helsinki declaration. In total, 24 male Sprague–Dawley rats weighing 250–280 g were used in this study. The animals were housed at 21°C and were given tap water and standard rat food ad libitum.

**Surgical procedure**

The animals were anesthetized via an intramuscular injection of ketamine hydrochloride (50–100 mg/kg of body weight). Twenty-four male rats were randomly assigned to three groups. Group I, no irrigation after the development of peritonitis; Group II, irrigation using isotonic solution in the 24th hour after the development of peritonitis; and Group III, irrigation using mesalazine solution in the 24th hour after the development of peritonitis.

Peritonitis was generated by small holes on the cecums of rats using a 22-G needle after laparotomy. Ten milliliter isotonic solution was abdominally administered to Group II and mesalazine (0.2 g/10mL) to Group III 24 h later (Fig. 1). A second laparotomy was performed in the 48th hour. Intracardiac blood samples were taken. Blood samples were collected for the measurement of TNFα, IL-1β, IL-6, and CRP levels. All rats were sacrificed 48 h after the first laparotomy. Tissue samples were taken from the lung.

**Cytokines measurement**

Samples were collected in serum separator tubes. After clot formation, samples were centrifuged at 1000×g for 10 min, and serum was collected. Serum was stored at −40°C until required for analysis. Cell signal proteins were assessed in the top supernatant of blood by TNF-α, IL-1β, IL-6, and CRP levels using an enzyme-linked immunosorbent assay kit in accordance with the manufacturer’s guidelines.

**Histologic analysis**

Lung tissue samples were taken from the rats for histopathologic investigation because the risk of development of multiple organ failure was mainly in the lung in sepsis. For histologic assessments, lung samples were obtained from eight anesthetized rats is each group at 48 h through excisional biopsy. All specimens were fixed in 10% buffered formalin. Paraffin blocks were prepared from routinely processed specimens, and 5-μm sections were cut and deparaffinized. The sections were stained using hematoxylin–eosin (H&E). Histopathologic examinations were performed by a blinded pathologist with light microscopy at ×200 magnification.

**DISCUSSION**

Secondary peritonitis is one of the main causes of sepsis and multiple organ failure. Its mortality rate is still high [7]. Elevated plasmacytokine levels have been related to the development of systemic inflammatory response syndrome, sepsis, and organ dysfunction.

TNF-α has been associated with patients at high-risk for sepsis after abdominal surgery and is a predictor of mortality [8, 9]. Qui P et al. [10] investigated the therapeutic role of anti-TNF agents in a meta-analysis study. They searched 15 studies and concluded that anti-TNF agents produced a modest but significant decrease in
High levels of CRP are caused by infections and many inflammatory diseases. The relationship between intra-abdominal infections and CRP is well established [11]. K. Mulari analyzed 66 patients with secondary peritonitis due to gastrointestinal tract perforation and investigated risk factors for hospital mortality. It was concluded that elevated CRP levels and high Mannheim peritonitis index score in the early postoperative phase had a prognostic significance [12].

Peritoneal lavage is described as the washing of the peritoneal space with high volumes of saline. Different agents have been used for peritoneal lavage in the literature. Povidone–iodine (PVI) and saline are well-known agents that are used for this purpose. Araujo ID et al. investigated peritoneal lavage with PVI in rats with experimental peritonitis. Lavage of the peritoneal cavity with PVI demonstrated no beneficial effect in local control of peritonitis [13]. Camargo M et al. showed a beneficial effect of peritoneal lavage with bupovacaine in rats with fecal peritonitis [14]. Peritoneal irrigation was performed in cases of severe pancreatitis and morbidity and mortality rates decreased in this patient group [15]. Coumarin, which has an immunostimulant effect, was used in peritonitis without any beneficial effect [16, 17]. Peritoneal irrigation performed with a local anesthetic agent, 0.2% ropivacarine, in rats with fecal peritonitis decreased the histologic changes that occurred due to inflammation [18].

In our study, Groups II and III underwent the proposed therapeutic process (peritoneal lavage with isotonic solution and mesalazine). The effects of peritoneal lavage with isotonic solution and mesalazine was exam-
ined objectively. The mean CRP level was found statistically significantly lower in Group III than in the other groups. TNFα and IL-1β levels were also lower in Group III. The decrease in TNF-α levels in Group III was statistically significant. We examined the lung tissues to show the systemic effect of intra-abdominal infection. The degree of inflammatory reaction was found lower in Group III, indicating that lavage using mesalazine may have a protective effect on the lung tissue.

CONCLUSION

In rats with intra-abdominal sepsis, TNF-α and CRP levels significantly decreased in the mesalazine group. There were also decrease in leukocyte infiltration in the lungs of rats treated with mesalazine. So, it may be suggested that the use of mesalazine in clinical practice may decrease the sepsis-related morbidity and mortality.
