ABSTRACT

Cushing’s syndromes (CS) due to thymic carcinoids are rarely seen. In this text, a case with CS due to ectopic adrenocorticotropic hormone (ACTH) secreting atypical thymic carcinoid tumor is presented. A 50-year-old Turkish male patient was admitted to our emergency department with typical CS features. Basal hormone profile, low- and high-dose dexamethasone suppression tests, and inferior petrosal sinus sampling results were consistent with ectopic ACTH secretion. Thorax computerized tomography showed an upper mediastinal mass, and trans-thoracic biopsy showed atypical thymic carcinoid with positive ACTH staining. Since the vascular invasion was detected, tumor was accepted inoperable; somatostatine receptor analogs, chemotherapy, and radiotherapy were planned. Ectopic CS can be derived from atypical thymic carcinoid. In this case, ACTH staining was used to confirm ACTH secretion from thymic tissue, and positive staining was detected. ACTH staining routinely was not performed for extra hypophyseal tissue tumors. In suspicious and difficult cases, ACTH staining can be helpful to confirm the presence of ACTH in tumor tissues.

Keywords: Ectopic Cushing’s syndrome; Carcinoid tumor; thymus.

CASE REPORT

A 50-year-old male patient was admitted to our emergency department with the complaint of fatigue and weight loss (nearly 8 kg for the past 2 years). In his history, he had hypothyroid and hypertensive for 3 years and treated with l-thyroxine, candesartan 16 mg with hydrochloride 12.5 mg in combination, and amlodipin 5 mg/day. On his physical examination, he was 180 cm in height and 80 kg in weight, body mass index was 24.6 kg/m², blood pressure was 130/80 mmHg. He had central obesity, plethora, acne, moon face, and dorsal fat pad. Chest X-ray showed upper mediastinal widening. Considering CS, 24-h urine free cortisol, plasma ACTH, and serum cortisol were measured and found as 953 µg/day (normal 36–137 µg/day), 257.9 pg/ml, and 32.8 µg/dl, respectively. Low-dose overnight dexamethasone suppression test (DST) and high-dose DST (8 mg) were unable to suppress serum cortisol levels (22 µg/dl and 25, 34 µg/dl, respectively). The diurnal rhythm was accessed, and serum cortisol levels were found as 18.62 µg/dl, 22.0 µg/dl, and 20.69 µg/dl at 00 00, 01 00, and 07 00, respectively, and considered abnormal (Table 1). Sella magnetic resonance imaging was normal. Inferior petrosal sinus sampling was performed, and the right-to-left ACTH ratio was found lower than 1.4. After the CRH administration central to peripheral ACTH ratio was found lower than 2, and these results were related with ectopic CS (Table 2). Since he had upper mediastinal widening, thorax computerized tomography (CT) was performed and showed a macrolobular mass in size of 67 mm × 49 mm with irregular border and calcification, and also invasion to brachiocephalic vein and pathological size paratracheal, subcarinal, and hilar lymphadenopathy in size up to 45 mm were detected (Fig. 1). Transthoracic tri-cut biopsy was performed, and pathological examination revealed atypical thymic carcinoid. Microscopically, tumor was composed of uniform cells with nested, trabecular, and rosette-like growth patterns. Polygonal tumor cells have moderate eosinophilic granular cytoplasm, round to oval nuclei, “salt and pepper” chromatin and inconspicuous nucleoli (Fig. 2). Focal necrosis and two mitoses per high power field (HPF) were seen. “Dot-like” staining pattern was detected with immune histochemical Pan-NK stain. Tumor cells were positive with immune histochemical ACTH, synaptophysin, and chromogranin staining (Fig. 2). Chromogranin A (Cg A) levels were found <5 ng/ml. Positron emission tomography and CT revealed an increased FDG uptake (SUV max: 11.99)

Results are given as pg/ml. ACTH: Adrenocorticotropic hormone; CRH: Corticotrophin-releasing hormone.

**Figure 1.** Axial thorax computerized tomography showed a macrolobular mass (white arrow) with irregular border and calcification, invasion to brachio-cephalic vein and pathological size paratracheal, subcarinal, and hilar lymphadenopathy.
in the mass and lymphadenopathy (SUV max: 7.76). With these findings, the patient was accepted as CS due to ACTH-secreting thymic carcinoid. Considering the patient inoperable, cisplatin (75 mg/m²), etoposide (100 mg/m²), somatostatin receptor analogs (SRA), and radiotherapy treatment were planned.

**DISCUSSION**

In this report, a case with CS due to ectopic ACTH secreting atypical thymic carcinoids is presented. Neuroendocrine tumors (NETs) of the thymus are classified as typical carcinoid, atypical carcinoid, and neuroendocrine carcinoma (large cell neuroendocrine carcinoma and small cell neuroendocrine carcinoma) [9]. Criteria to distinguish these tumors are based on mitoses and necrosis. Atypical carcinoid can be diagnosed with bifocal necrosis and/or 2–10 mitoses per 10 HPF is detected in a NET [9]. Main pathological differential diagnosis of atypical thymic carcinoid is metastatic low-grade neuroendocrine carcinoma, thymic epithelial tumor with neuroendocrine differentiation, paraganglioma, and type A thymoma [9]. Atypical thymic carcinoids are more aggressive than typical ones, and the survival rate is low [5, 6, 10]. Another clinical importance of carcinoids is that it can be complicated by endocrine abnormalities. ACTH secretion from thymic carcinoid is a very rare condition and has been described only in limited numbers [1-3, 7, 8, 11-13]. ACTH-dependent CS may result from ectopic ACTH production; and, it is usually difficult to distinguish from hypophyseal - ACTH secretion. Underlying slow-growing tumor, such as carcinoids, can mimic Cushing's disease. Rarely can these tumors be cyclic secretary and to carry out dynamic endocrine tests during this period is often inconclusive. In addition, most of these tumors are occult, and it is difficult to detect the source of ACTH production [14]. In this case, higher plasma ACTH levels and no suppression were detected during low- and high-dose DST. IPSS was compatible with ectopic ACTH secretion, and thorax CT revealed a thymic mass, as we considered ectopic ACTH syndrome due to thymic cancer, a biopsy was performed, and atypical carcinoid was detected. To confirm the ACTH source from this tissue, ACTH staining was performed and positive staining was detected. Despite the fact that, Cg is a useful marker for the diagnosis and follow-up of NETs, serum Cg A levels were determined normal in our case. In a recently published review, the sensitivity, specificity, positive predictive value, and negative predictive value were reported 84.2%, 78.2%, 41.5%, and 96.4%, respectively, in the NET diagnosis of Cg A. For this reason, it is important to remember that normal Cg A levels in NETs are not always guiding [15].

Treatment options of thymic carcinoids are surgical excision, chemotherapy, SRA, and radiotherapy. Due to aggressivity of the atypical carcinoid tumor, lesions are commonly diffuse and multifocal; therefore, the surgical cure can be achieved only in limited patients. Likewise, although different chemotherapy regimens are recommended, the success rate is <30% [16]. In a recent study of 30 patients with thymic NET, 5 and 10-year survival was determined as 77% and 30%, respectively, and it was reported that survival was better in patients whose tumor was [17]. New anticancer drugs success rates seem to in-
crease much more. Crona et al. reported the efficacy of temozolomide or platinum-based chemotherapy as median time in the first treatment of 28 patients with high Ki 67 index or thymic carcinoid resected wholly macroscopically as 20.5 and 18 months, respectively [18].

As carcinoid tumors have expressed somatostatin receptors, SRA can be used for suppression of tumor growth and ectopic hormone secretion [19]. In addition, somatostatin receptor scintigraphy (SRS) can help to distinguish thymic pathologies from simple thymic hyperplasia and to show distant metastases [20]. However, we could not do SRSs due to technical inadequacies. In our case, due to vascular invasion and multiple lymphadenopathies, surgery was not preferred for initial therapy instead of lanreotide, cisplatin, and etoposide treatments were started, and conventional radiotherapy was planned.

**Conclusion**

Ectopic CS can be derived from atypical thymic carcinoid. In this case, we used ACTH staining in thymic tissue to confirm ACTH secretion from these tissues, and positive staining was detected. Routinely, ACTH staining was not performed for extrahypophysial tissue tumors. In difficult cases, ACTH staining can be helpful to confirm the presence of ACTH secretion in tumor tissues.
