## Abstract

**Objective:** The *JAK2V617F* mutation is present in the majority of patients with essential thrombocythemia (ET) and primary myelofibrosis (PMF). The impact of this mutation on disease phenotype in ET and PMF is still a matter of discussion. This study aims to determine whether there are differences in clinical presentation and disease outcome between ET and PMF patients with and without the *JAK2V617F* mutation.

**Materials and Methods:** In this single-center study, a total of 184 consecutive Philadelphia-negative chronic myeloproliferative neoplasms, 107 cases of ET and 77 cases of PMF, were genotyped for *JAK2V617F* mutation using the *JAK2* Ipsogen MutaScreen assay, which involves allele-specific polymerase chain reaction.

**Results:** ET patients positive for *JAK2V617F* mutation had higher hemoglobin (Hb) and hematocrit (Hct) levels, lower platelet counts, and more prevalent splenomegaly at diagnosis compared to patients negative for the *JAK2V617F* mutation, but rates of major thrombotic events, arterial thrombosis, and venous thrombosis were comparable between the groups. At presentation, PMF patients with *JAK2V617F* mutation had significantly higher Hb and Hct levels and leukocyte counts than patients without the mutation. Similar to the findings of ET patients, thromboembolic rates were similar in PMF patients with and without the *JAK2V617F* mutation. For ET and PMF patients, no difference was observed in rates of death with respect to *JAK2V617F* mutational status. Moreover, leukemic transformation rate was not different in our PMF patients with and without *JAK2V617F* mutation.

**Conclusion:** We conclude that *JAK2V617F*-mutated ET patients express a polycythemia vera-like phenotype and *JAK2V617F* mutation in PMF patients is associated with a more pronounced myeloproliferative phenotype.

**Keywords:** *JAK2V617F* mutation, Essential thrombocythemia, Primary myelofibrosis

## Öz

**Amaç:** Esansiyel trombositemi (ET) ve primer miyelofibrozis (PMF) tanılı hastaların büyük çoğunluğunda *JAK2V617F* mutasyonu bulunmaktadır. ET ve PMF'de bu mutasyonun hastalık fenotipi üzerine etkisi halen tartışılmaktadır. Bu çalışmada, *JAK2V617F* mutasyonunu taşıyan ve taşımayan ET ve PMF hastalarının başvuru sırasındaki klinik parametreler ve hastalık seyri açısından karşılaştırılması amaçlanmıştır.

**Gereç ve Yöntemler:** Tek merkezli olan bu çalışmada, 107 ET ve 77 PMF olmak üzere toplam 184 Philadelphia-negatif kronik miyeloproliferatif neoplazili hastada bir allel spesifik polimeraz zincir reaksiyonu olan *JAK2* Ipsogen MutaScreen kullanılarak *JAK2V617F* mutasyonu taranmıştır.

**Bulgular:** *JAK2V617F* mutasyonunu taşıyan ET hastalarında, mutasyon bulunmayanlara göre tanı sırasındaki hemoglobin (Hb) ve hematokrit (Hct) düzeyleri anlamlı olarak daha yüksek, trombosit sayısı daha düşük ve splenomegali oranları daha yüksek bulunmuştur. Fakat her iki grup arasında majör trombotik olay, arteriyel tromboz ve venöz tromboz açısından fark saptanmamıştır. *JAK2V617F* mutasyonu bulunan PMF hastalarında ise mutasyon taşımayan gruba göre başvuru anındaki Hb, Hct ve lökosit değerleri anlamlı olarak daha yüksek saptanmıştır. PMF hastalarında, ET hastalarında olduğu gibi tromboembolik olayların *JAK2V617F* mutasyonundan bağımsız olduğu görülmüştür. ET ve PMF hastalarında *JAK2V617F* mutasyonu varlığında ölüm oranında farklılık gözlenmemiştir. Bunun yanında *JAK2V617F* mutasyonunu taşıyan ve taşımayan PMF hastaları arasında lösemik dönüşüm oranı açısından anlamlı bir fark bulunmamıştır.

**Sonuç:** Bu çalışmanın sonucunda *JAK2V617F* mutasyonunu taşıyan ET hastalarında polisitemia vera benzeri fenotipin ortaya çıktığı ve bu mutasyonun varlığında PMF hastalarının daha belirgin bir miyeloproliferatif fenotiple ilişkili olduğu söylenebilir.

**Anahtar Sözcükler:** *JAK2V617F* mutasyonu, Esansiyel trombositemi, Primer miyelofibrozis

## Introduction

Philadelphia-negative chronic myeloproliferative neoplasms (Ph-negative MPNs) are a heterogeneous group including 3 major diseases: polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF). Thrombotic events are the major cause of morbidity and mortality in ET. Other complications include hemorrhage and progression to myelofibrosis or acute myeloid leukemia [1,2]. PMF is characterized by a worse life expectancy and a progressive disease course. The disease presents with classically severe anemia, massive splenomegaly, and acute leukemia [3]. *JAK2V617F* mutation is present in more than 95% of PV patients and approximately 50%-60% of ET and PMF patients [4]. Several studies investigated the clinical relevance of *JAK2V617F* mutation in ET and PMF patients [5,6,7,8,9,10]. In ET, overall survival (OS) or leukemia-free survival was found not to be affected by the presence of *JAK2V617F* mutation, while the influence of *JAK2V617F* on thrombosis or fibrotic transformation remained less clear [5,7,11,12]. Conflicting results have been reported regarding the impact on OS, leukemic transformation rate, and need for chemotherapy or splenectomy in the presence of *JAK2V617F* mutation [8,9,10,13]. We previously evaluated the clinical and laboratory correlates in 184 patients with Ph-negative MPNs according to the allele burden of *JAK2V617F* mutation (unpublished data). Herein, we investigate the usefulness of *JAK2V617F* mutational status for explaining phenotypic variability using the same group of patients, which includes a relatively large series of Ph-negative MPN patients.

## Materials and Methods

A total of 184 consecutive Ph-negative MPN patients, 107 with ET and 77 with PMF, admitted to the Division of Hematology of the İstanbul University İstanbul Medical Faculty from 1995 to 2013 were included in the study. ET and PMF patients were diagnosed based on WHO criteria [14]. Informed consent was obtained from all participants according to the local ethics committee guidelines. Complete clinical history, blood count, lactate dehydrogenase (LDH) level, and thrombotic or hemorrhagic complications were recorded. Spleen longitudinal diameters of  $\geq 130$  mm to 160 mm and of  $\geq 160$  mm on ultrasound were considered as mild and massive splenomegaly, respectively. A scale of 0-3 was used to grade reticulin fibrosis on bone marrow trephine biopsies [15]. The Dynamic International Prognostic Scoring System (DIPSS) plus was used for risk stratification in PMF [16]. Unfavorable karyotypes in PMF were defined as complex karyotype or sole or 2 abnormalities that included +8, -7/7q-, i(17q), inv(3), -5/5q-, 12p-, or 11q23 rearrangement [17]. Patients were genotyped for the *JAK2V617F* mutation by *JAK2* MutaScreen assay (Ipsogen, Luminy Biotech, Marseille, France), which is a TaqMan allelic discrimination assay that contains fluorescent probes specific for wild-type (617V) and mutant (617F) alleles [18].

## Statistical Analysis

Data were processed using SPSS 16 (SPSS Inc., Chicago, IL, USA). Continuous variables were summarized as mean [standard deviation (SD)]. Chi-square statistics were used to compare categorical variables among the different patient groups categorized according to the *JAK2V617F* mutational status. Analysis of continuous variables among the groups was performed using the Mann-Whitney U test. A p-value of less than 0.050 was considered to indicate statistical significance; all tests were 2-tailed.

## Results

A total of 184 patients (107 with ET and 77 with PMF) were included. Bone marrow fibrosis was detected in 90.7% (97 in 107) of ET and 100% of PMF patients. In ET patients, the grade of bone marrow fibrosis was scaled as follows: grade 0, 9.3%; grade 1, 62.7%; grade 2, 25.2%; and grade 3, 2.8%. All PMF patients had bone marrow fibrosis (grade 2 in 20.8% and grade 3 in 79.2%).

*JAK2V617F* mutation was identified in 64 of 107 ET (59.8%) and 58 of 77 PMF (75.3%) patients ( $p=0.028$ ). Clinical and laboratory correlates of ET patients according to *JAK2V617F* mutational status are summarized in Tables 1 and 2.

*JAK2V617F*-positive and -negative ET patients showed no significant differences with respect to sex and age at diagnosis. ET patients with *JAK2V617F* mutation presented with higher hemoglobin (Hb) and hematocrit (Hct) levels and lower platelet count at diagnosis compared to patients without mutation ( $p=0.001$ ,  $p=0.001$ , and  $p=0.043$ , respectively). The leukocyte count and LDH levels were similar for the 2 groups.

The 2 groups showed no significant difference with respect to mean spleen size. However, *JAK2V617F*-positive ET patients presented with more prevalent splenomegaly at diagnosis compared to patients without the mutation ( $p=0.044$ ).

ET patients with *JAK2V617F* mutation showed a higher, albeit not statistically significant, rate of bleeding events compared to the *JAK2V617F*-negative group (15.6% and 7%, respectively;  $p=0.298$ ).

ET patients with and without *JAK2V617F* mutation showed no significant difference with respect to the degree of bone marrow fibrosis, prevalence of hydroxyurea use, and rate of splenectomy. In addition, no significant differences were observed in the use of other medical treatments in any of the categories ( $p>0.050$ ). Duration of follow-up in patients with and without *JAK2V617F* mutation was 69.7 months (SD: 63.7) and 70.1 months (SD: 56.9), respectively ( $p=0.675$ ). During follow-up, 3 of 64 (4.7%) *JAK2V617F*-positive ET and 2 of 43 (4.7%) *JAK2V617F*-negative ET patients succumbed to their disease ( $p=1.000$ ).

Clinical and laboratory parameters of PMF patients classified according to genotype are outlined in Tables 3 and 4.

The rate of female patients was higher in the *JAK2V617F*-negative group compared to the *JAK2V617F*-positive group (84.2% and 46.6%, respectively;  $p=0.009$ ). PMF patients with and without *JAK2V617F* mutation showed no significant differences with respect to age at diagnosis. At initial diagnosis, PMF patients with the *JAK2V617F* mutation presented with significantly higher Hb and Hct levels and leukocyte counts compared to those without the mutation ( $p=0.005$ ,  $p=0.034$ , and  $p=0.046$ , respectively). Platelet count and LDH level did not differ between the 2 groups.

The mean spleen size showed no significant difference among any of the categories, although PMF patients with *JAK2V617F* mutation showed a trend towards higher prevalence of massive splenomegaly at diagnosis compared to patients without mutation ( $p=0.193$  and  $p=0.090$ , respectively).

*JAK2V617F*-positive PMF patients showed a trend towards a higher prevalence of bleeding events compared to *JAK2V617F*-negative PMF patients (24.1% and 5.3%, respectively;  $p=0.090$ ).

There was no significant difference in the prevalence of total thrombotic events, arterial thrombosis, and venous thrombosis between *JAK2V617F*-positive and -negative PMF patients.

The degree of reticulin fibrosis, prevalence of hydroxyurea use, rate of allogeneic hematopoietic stem cell transplantation (AH SCT), and history of splenectomy did not differ in any of the categories. In addition, the 2 groups showed no significant differences in the use of other medical treatments ( $p>0.050$ ).

No significant difference was observed in the distribution of karyotype categories and DIPSS-Plus risk stratification between *JAK2V617F*-positive and -negative PMF patients.

Duration of follow-up in PMF patients with and without *JAK2V617F* mutation was 42 months (SD: 46.9) and 56.6 months (SD: 48.7), respectively ( $p=0.165$ ). At the end of the data collection period, 11 of 58 (19%) PMF patients with *JAK2V617F* mutation succumbed to their disease, while the rate of death in patients without *JAK2V617F* mutation was 15.8% ( $p=1.000$ ). During follow-up, rate of leukemic transformation was similar between the 2 categories.

## Discussion

In our relatively large series of patients with Ph-negative MPNs, including 107 ET patients with a mean follow-up duration of more than 5 years and 77 PMF patients with a mean follow-up duration of more than 3 years, we documented that *JAK2V617F* mutation correlates with disease phenotype in adult Turkish patients with ET and PMF.

Our results suggest that *JAK2V617F* positivity in ET induces a phenotype resembling PV. Confirming previous observations, we found that ET patients with *JAK2V617F* mutation presented with higher Hb and Hct levels and lower platelet counts compared to unmutated patients [5,6,7,19,20,21,22]. Contrary to some previous reports yet consistent with the findings of Kittur et al. [5] and Pich et al. [22], our ET patients with *JAK2V617F* mutation showed no difference in leukocyte count at diagnosis as opposed to patients without the mutation [6,21]. Furthermore, in contrast to some previous reports but consistent

with the study of Vannucchi et al. [11], we observed a higher prevalence of splenomegaly in ET patients with *JAK2V617F* mutation than in patients without the mutation [5,6,7,20,21]. Data on ET regarding the impact of *JAK2V617F* mutational status on thrombotic events are conflicting. In the study by Campbell et al., *JAK2V617F* mutation in ET was associated with an increased frequency of venous thromboembolism, but not with arterial thrombosis [6]. In the study by Kittur et al., the presence of *JAK2V617F* mutation was found to be significantly associated with increased incidence of venous thrombosis during follow-up, but not with major thrombosis, arterial thrombosis, and venous thrombosis at diagnosis [5]. In contrast, Antonioli et al. reported that there was no correlation between thrombotic events and *JAK2V617F* mutation in ET patients [20]. In another study, there was no difference between ET patients with *JAK2V617F* mutation or wild-type alleles with respect to the frequency of major thrombotic events and major arterial and venous thrombosis, either at diagnosis or during follow-up [21]. Similar to the aforementioned study in ET patients, the presence of *JAK2V617F* mutation made no significant difference in the frequency of vascular complications at presentation [7]. In the current study, we observed no significant difference in the frequency of major thrombotic events, arterial thrombosis, and venous thrombosis between *JAK2V617F*-positive and -negative ET patients. In the study by Pich et al., ET patients with *JAK2V617F* mutation were younger than those without mutation [22]. Conversely, in several studies, the presence of *JAK2V617F* mutation was significantly associated with older age at diagnosis [5,7,11,21,23,24,25]. Some studies revealed no difference in age between *JAK2V617F*-positive and -negative ET patients [20,26]. In our study group, we found no significant difference in age among ET patients with and without *JAK2V617F* mutation. Moreover, in the current study, we did not determine an association between *JAK2V617F* mutation and sex, consistent with previous reports [5,7,11,20,21,23,24,25,26]. Alvarez-Larrán et al. reported that the presence of *JAK2V617F* mutation in ET patients was associated with increased LDH levels [25]. On the contrary, in another study, *JAK2V617F* mutation in ET did not correlate with LDH level [21]. Our ET patients with *JAK2V617F* mutation did not show differences in LDH level as compared to wild-type patients. To our knowledge, there is limited information about the association between *JAK2V617F* mutation and histological changes in bone marrow biopsy of ET patients. In a series of 103 ET patients, Pich et al. reported no significant impact of *JAK2V617F* mutation on bone marrow fibrosis [22]. In the current study, the presence of *JAK2V617F* mutation in ET did not correlate with the degree of reticulin fibrosis. Several studies investigated the association between *JAK2V617F* mutation in ET and major hemorrhages [7,11,20,21,25]. Confirming the findings of the aforementioned studies, our ET patients with mutant and wild-type alleles showed no differences in the rate of bleeding complications [7,11,20,21,25]. Some previous studies reported

that cytoreductive therapy requirement did not differ between ET patients with and without *JAK2V617F* mutation [7,21,23,24]. This finding is in line with our data showing that the prevalence of hydroxyurea use and other medical treatments was similar between *JAK2V617F*-mutated and -unmutated ET patients [7,21,23,24]. In ET patients, OS was shown not to be influenced by the presence of *JAK2V617F* mutation [5,7]. Confirming this observation, the death rate did not differ in our ET patients with and without *JAK2V617F* mutation.

In our series of 77 PMF patients, we found a significant association between *JAK2V617F* mutation and the expression of a more pronounced myeloproliferative phenotype. In PMF patients, *JAK2V617F* mutational status contributed to laboratory abnormalities, including higher Hb level and leukocyte count, but its association with platelet count is inconsistent [19]. Our PMF patients with *JAK2V617F* mutation had higher Hb and Htc levels and leukocyte counts at diagnosis than those without the mutation. In contrast, in our PMF patients, platelet count at initial diagnosis did not differ with respect to the *JAK2V617F* mutation. Barosi et al. demonstrated the association between *JAK2V617F* mutational status and development of marked splenomegaly [9]. On the other hand, in this population, several other groups did not show any correlation between the presence of *JAK2V617F* mutation and spleen size [8,10]. In the study by Guglielmelli et al., *JAK2V617F* mutated and wild-type patients did not differ from each other as regards the presence of palpable splenomegaly greater than 15 cm from the left costal margin [27]. In our study, the mean spleen size did not significantly differ between *JAK2V617F*-positive and -negative PMF patients, although PMF patients with *JAK2V617F* mutation showed a trend towards higher prevalence of massive splenomegaly at diagnosis compared to patients without mutation. In PMF patients, the relationship of *JAK2V617F* mutation and thrombosis is controversial. In the study by Barosi et al., there was no significant difference in the rate of major thrombotic events between *JAK2V617F*-mutated and -unmutated PMF patients [9]. In a series of 199 PMF patients, Tefferi et al. showed no significant difference in the prevalence of thrombosis between *JAK2V617F*-positive and -negative PMF patients, whereas in another series of 117 PMF patients, Tefferi et al. reported the association of the presence of *JAK2V617F* mutation with history of thrombosis [8,13]. In the current study, the prevalence of total thrombotic events, arterial thrombosis, and venous thrombosis did not significantly differ among PMF patients with and without *JAK2V617F* mutation. Several studies have shown that ET patients with mutant alleles and wild-type alleles showed no significant difference with respect to age and sex [8,10,27]. In the current study, the presence of *JAK2V617F* mutation in PMF patients was not associated with age. However, in our study, the rate of females was higher among *JAK2V617F*-negative PMF patients than *JAK2V617F*-positive PMF. We did

not find a significant difference in LDH level between PMF patients with and without *JAK2V617F* mutation, in accordance with some previous reports [8,10,27]. In a study involving 117 patients with PMF, the presence of *JAK2V617F* mutation did not correlate with degree of reticulin fibrosis [8]. Consistent with the study by Tefferi et al., the degree of reticulin fibrosis did not differ between our PMF patients when stratified by *JAK2V617F* mutational status [8]. There is limited information regarding the relevance of *JAK2V617F* on bleeding complications in PMF patients. Tefferi et al. did not determine a statistically significant correlation between *JAK2V617F* mutation and bleeding history

[8]. However, we observed a trend towards higher prevalence of bleeding events in *JAK2V617F*-positive PMF patients compared to *JAK2V617F*-negative PMF patients (24.1% and 5.3%, respectively). In the study by Barosi et al., *JAK2V617F* mutational status was associated with an increased requirement for splenectomy and greater need of cytoreductive therapy in PMF patients [9]. However, in the study by Tefferi et al. involving 199 patients with PMF, no significant correlation was found between the presence of *JAK2V617F* mutation and need for cytoreductive therapy or splenectomy [13]. Confirming the finding of Tefferi et al., in our study, the presence of *JAK2V617F* mutation in

Death	11 (19%)	3 (15.8%)	1.000

PMF: Primary myelofibrosis, AHSCT: allogeneic hematopoietic stem cell transplantation, DIPSS: Dynamic International Prognostic Scoring System.

PMF had no impact on the need for cytoreductive treatment or requirement for splenectomy [13]. Several studies investigated the association of *JAK2V617F* mutation in PMF patients with prognostic scoring systems [8,10,13,27]. In a series of 186 PMF patients, the number of *JAK2V617F*-positive patients in the low risk category of the Dupriez scoring system was significantly higher compared with *JAK2V617F*-negative patients [27]. Campbell et al. reported that Dupriez prognostic scores tended to be lower for patients positive for *JAK2V617F* mutation [10]. On the contrary, several groups reported no correlation between *JAK2V617F* mutation and Dupriez prognostic score [8,13]. To analyze whether the *JAK2V617F* mutational status correlated with prognostic scoring systems, we evaluated the distribution of patients in the different risk categories of the DIPSS-Plus [16]. We found no significant difference in the DIPSS-Plus risk stratification between *JAK2V617F*-positive and -negative PMF patients. Several studies revealed that in PMF, the presence of *JAK2V617F* mutation showed no correlation with presence or

distribution of cytogenetic abnormalities [8,9,10]. Confirming the aforementioned studies, in our population, we observed no significant difference in the distribution of karyotype categories between *JAK2V617F*-positive and -negative groups. Divergent results were reported regarding the effect of *JAK2V617F* mutation on OS and leukemic transformation rate in PMF patients [8,9,10,13]. We did not observe any differences in the rates of death and leukemic transformation in PMF patients with and without *JAK2V617F* mutation.

Collectively, according to the results of our study, *JAK2V617F* mutation may identify distinct disease phenotypes of ET and PMF patients.

#### Acknowledgment

We thank the Molecular Hematology Laboratory staff of the İstanbul University İstanbul Medical Faculty for their assistance with sample handling.

## Ethics

Ethics Committee Approval: The study was approved by the Local Ethics Committee of İstanbul University İstanbul Medical Faculty (file number: 2012/1571-1245), Informed Consent: Informed consent was obtained from all patients for being included in the study.

## Authorship Contributions

Design the Research: İpek Yönel, Meliha Nalçacı, Akif Selim Yavuz, Fatma Deniz Sargın; Concept: İpek Yönel, Meliha Nalçacı, Akif Selim Yavuz; Supply Samples: İpek Yönel; Analyze the Data: İpek Yönel; Literature Search: İpek Yönel; Draft the Article: İpek Yönel, Aynur Dağlar-Aday, Başak Akadam-Teker, Ceylan Yılmaz; Perform the Laboratory Work: Aynur Dağlar-Aday, Başak Akadam-Teker, Ceylan Yılmaz; Help in Acquisition of Data: Aynur Dağlar-Aday, Başak Akadam-Teker, Ceylan Yılmaz; Revise the Article: Meliha Nalçacı, Akif Selim Yavuz, Fatma Deniz Sargın; Writing: İpek Yönel, Aynur Dağlar-Aday, Başak Akadam-Teker, Ceylan Yılmaz, Meliha Nalçacı, Akif Selim Yavuz, Fatma Deniz Sargın.

Conflict of Interest: The authors of this paper have no conflicts of interest, including specific financial interests, relationships, and/or affiliations relevant to the subject matter or materials included.

Financial Disclosure: The study was supported by the İstanbul University Scientific Research Foundation (project number: 30427).
