Reverse Takotsubo cardiomyopathy following intra-abdominal surgery

Karın içi cerrahi sonrası meydana gelen Ters Takotsubo kardiyomiyopatisi

Summary– Reverse Takotsubo cardiomyopathy (RTC) is a rare condition characterized by systolic dysfunction of the basal segments of the left ventricle in the absence of obstructive coronary artery disease. The case of a 50-year-old woman with RTC following intra-abdominal surgery is described in the present report.

Özet– Ters Takotsubo kardiyomiyopatisi (KMP) kalbin daha çok bazal segmentlerini etkileyen ve anlamlı koroner darlığın olmadığı nadir bir kalp yetersizliği sebebidir. Bu yazida, 50 yaşında kadın hastada karın içi cerrahi sonrası gelişen ters Takotsubo kardiyomiyopatisi sunuldu.

CASE REPORT

A 51-year-old woman presented to the cardiology department with chest pain and dyspnea after having undergone laparoscopic cholecystectomy a day earlier. Her medical history was unremarkable, with no cardiac disease. The patient had blood pressure of 110/70 mm Hg, respiratory rate of 22 breaths per minute, and oxygen saturation of 93%. Cardiac examination revealed no heart murmur. Mild cardiomegaly and increased pulmonary congestion were seen on chest x-ray. Electrocardiography revealed inverted T waves and ST-segment depression in V4—V6 leads (Figure 1a, b). Laboratory examination showed elevated troponin levels. Coronary angiography showed normal coronary arteries with no coronary stenosis. Echocardiographic examination revealed hypokinetic basal segment of the myocardium, with hyperkinetic apical segments on echocardiography.

In the present report, a patient with RTC following intra-abdominal surgery is described.

DISCUSSION

TCM is a well-recognized clinical syndrome of reversible left ventricular dysfunction that typically involves the apical segments and appears with normal coronary arteries.[1] In contrast to classic TCM, RTC is stress-induced and involves the basal and midven-

tricular segments, while the contractility of the apical segments is preserved. \[^3\] Wall-motion abnormalities and left ventricular dysfunction are completely reversible in the majority of cases. \[^4\]

Clinical presentation of RTC mimics acute coronary syndrome and may include symptoms of chest pain, shortness of breath, elevated cardiac enzymes, and ischemia or acute myocardial infarction detected on electrocardiogram. \[^4\] In addition, patients may present with severe left ventricular dysfunction, acute heart failure, and cardiogenic shock. \[^5\]

While the mechanism of TCM is still uncertain, it appears often to be triggered by emotional or physical stress. \[^5\] Pathophysiology relies on 2 primary theories: vascular dysfunction and induction by catecholamine. \[^6\] It has been proposed that variations in the density of adrenoceptors on the myocardial segments cause change in the distribution of wall-motion abnormalities. In cases of RTC, a majority of adrenoceptors may be found in the basal segments of the myocardium. \[^7\]
There are no guidelines for TCM treatment, and no randomized, double-blind studies have been conducted. Treatment is primarily empirical and must be individualized. It must follow current heart failure and coronary artery disease guidelines, and be managed according to guidelines for diagnosis and treatment of acute coronary syndromes. Diagnosis must involve detailed medical history, electrocardiography, echocardiography, coronary angiography, and troponin testing. Following diagnosis, supportive care usually leads to spontaneous recovery. Supportive therapy should include beta-blockers as initial treatment, in addition to ACE-inhibitors or angiotensin II blockers, as TCM is associated with transient left ventricular dysfunction.

The present patient was treated with beta-blocker and ACE-inhibitor. No other complications were present. Clinical and echocardiographic findings were normal on 61-day follow-up.
